Sir,

We report a 30 year-old woman with a history of lumpectomy for a benign breast tumor, presented with a 10-year history of an exophytic lesion of the scalp. The physical examination revealed a giant mass on the scalp, which was immobile, tender and exhibited distinct borders. A total excision of the lesion was performed. Grossly, the tumor was nodular, exophytic, and measured 19 cm of diameter. Histological examination showed a tumor consisting of spindle to epitheloid cells forming micro nodules in a concentric whorled shape pattern (Fig 1) embedded in abundant myxoid stroma (Fig. 2). These features confirmed the diagnosis of a neurothekoma. At 3 years of follow-up, the patient was asymptomatic and there was no recurrence.

The patient’s informed consent was obtained.

Prior to the study, patient gave written consent to the examination and biopsy after having been informed about the procedure.

Neurothekoma (NT) is an uncommon and benign dermal tumor, originating from the sheath of peripheral nerves. It is mainly located on the face, neck, arms and shoulders of young adults, and is more frequent in females [1,2].

Clinically, it manifests as an asymptomatic, pink-erythematous, dome-shaped, solitary papule or nodule, with a slow growth rate [2]. The clinical differential diagnosis of NT includes epidermal cyst, dermatofibroma, adnexal tumor (e.g. pilomatricoma), Fibrohistiocytic tumor, Basal cell carcinoma, hemangioma, amelanotic melanoma and cutaneous metastasis [2].

Histological examination shows the presence of spindle and epithelioid cells with abundant granular-cosinophilic cytoplasm and a tendency to be grouped in whorled nodules spared by collagen bundles in the dermis and subcutaneous area. There may be selerotic
collagen and osteoclast-like cells [3]. Furthermore, this tumor is subclassified histopathologically into 3 groups: myxoid, mixed, and cellular type depending on the amount of myxoid matrix [4]. Immunohistochemically, the S100 protein is useful to differentiate the myxoid type from the cellular type. The tumor cells of the cellular variant are not generally stained with markers for nerve-origin cells, but are positively stained with NKI/C3, Ki-M1p, and CD68 [4].

The histological differential diagnosis includes melanocytic tumor variants (e.g. Spitz Nevus), neurofibroma, schwannoma or neuroma variants [2]. An atypical variant of NT has recently been described. It is described like a larger tumor (up to 6cm) of deep penetration (skeletal muscle and subcutaneous fat involvement), diffuse infiltrative borders, vascular invasion, a high mitotic index (>3 mitosis per 10 high power fields) and pleomorphism [5].

The real recurrence of NT is around 3%. Risk factors for recurrence are: myxoid type, being female, facial location, younger age at diagnosis, positive margins, and absence of fat-tissue in the sample [3].

CONCLUSION

Neurothekoma is a rare tumor. The diagnosis is based on histopathological and eventually immunohistochemical exam. The evolution is marked by the risk of recidive.

Consent

The examination of the patient was conducted according to the Declaration of Helsinki principles. Written informed consent was obtained from the patient for publication of this article.
