INTRODUCTION

Tuberculosis is one of the most established known illnesses with confirmation of the disease being found in the vertebræ of neolithic man in Europe and in Egyptian mummies. It was not until 1882 that Robert Koch discovered the causative agent Mycobacterium tuberculosis [1]. In 2007, India positioned first in terms of aggregate number of TB cases (2.0 million) globally. Cutaneous tuberculosis constitutes about 1.5% of all extra pulmonary tuberculosis [2]. Various clinical forms of the disease have been reported, many of which closely mimic other common dermatoses in the tropics.

CASE REPORT

A 52 year old female came to dermatology OPD with complaints of multiple raised skin lesions over left leg and foot since 20 years. c/o discharge and pain over the lesion since 15 days. She initially developed a blister over left foot and swelling over left leg following trauma while cutting woods. The bulla spontaneously ruptured leaving an ulcer slowly healed and was recurrent which gradually developed into asymptomatic raised lesion over the left leg. No history of antituberculous therapy. No history of contact with open case of tuberculosis. On general examination left leg pitting pedal edema was present. Systemic examination did not reveal any abnormality. Cutaneous Examination revealed three well defined erythematous to flesh coloured soft nodules over left lower leg with surrounding hyperpigmented scaly plaque. A well defined hyperpigmented verrucous plaque with central depigmentation over left foot. Lupus vulgaris and chromoblastomycosis were the provisional diagnosis. Mantoux test was positive. Biopsy was suggestive of TBVC. Patient was treated with anti-tuberculous therapy. TBVC usually presents as a single verrucous lesion over exposed areas of the body. Our patient here presented with multiple nodules and hyperpigmented plaque over the left lower limb which was mimicking chromoblastomycosis.

Key words: Tuberculosis verrucosa cutis; Tubercle bacilli; Chromoblastomycosis
from the margin of the plaque was negative for mycelia/spores.

Mantoux Test – Positive (Figs. 3a and 3b).

To confirm the diagnosis an incision biopsy was taken from the nodule and the verrucous lesion (Figs. 1 and 2). The specimen was sent for Histopathological examination and fungal culture.

HPE of specimen A

PAS staining for fungus was negative. Culture for mycobacteria and fungi revealed no growth after 6 weeks.

Based on the clinical features and histopathology a diagnosis of tuberculosis verrucosa cutis was made (Figs. 1, 2 and 4).

The patient was started on DOTS category 1 regimen comprising of:

![Figure 1: Three well defined erythematous to pinkish soft nodules of size 1.5 cm over anterior aspect of left lower leg with surrounding hyperpigmented scaly plaque.](image)

![Figure 2: A well defined hyperpigmented plaque with central depigmentation with thick verrucous surface of size 5 x 3 cm over lower aspect of left leg. Diffuse swelling seen over the left leg with xerosis.](image)

![Figure 3a: Mantoux Test Positive.](image)

![Figure 3b: Mantoux Test Positive.](image)

![Figure 4: Histopathology showing Hyperkeratosis, acanthosis, papillomatosis, granulomas composed of lymphocytes, neutrophils, giant cells with central caseous necrosis.](image)
(2)HRZE + (4)HRE (Intensive phase - Isoniazid, Rifampicin, Pyrazinamide and Ethambutol for 2 months+ continuos phase - Isoniazid, Rifampicin, Ethambutol for 4 months).

There was regression of size of the lesion and also the verrucosity after 6months of therapy.

Prior to the study, patient gave written consent to the examination and biopsy after having been informed about the procedure.

DISCUSSION

Cutaneous tuberculosis forms a small proportion of extrapulmonary tuberculosis. Tuberculosis verrucosa cutis (TBVC) is a form of secondary (reinfection) tuberculosis occurring in presensitized individuals with a moderate to high degree of immunity.

Tuberculosis verrucosa cutis (TVC) also known as prosector’s wart of Laennec [3], verruca necrogenica, anatomic tubercle, lupus verrucosus, and butcher’s wart [4] is a paucibacillary form of cutaneous tuberculosis which occurs due to exogenous inoculation of tubercle bacilli into the skin in a previously sensitized patient [3] with a moderate to high degree of immunity [4]. The incidence of cutaneous tuberculosis has fallen from 2% to 0.15% [4]. TVC is frequently found on the hands and in areas prone to trauma. In tropical areas, the buttocks and lower extremities are commonly affected sites. The lesion starts as a papule or papulopustule also, gradually enlarges to form a verrucous plaque. It is much of the time misdiagnosed as a wart. Spontaneous healing may occur at the centre and the entire lesion may resolve after several months or years [5].

The histopathological features are characterized by marked pseudoepitheliomatous hyperplasia of the epidermis and the dermis show dense inflammatory infiltrates comprising of neutrophils, lymphocytes and giant cells [3].

Cutaneous tuberculosis still remains a puzzle to todays dermatologists as a result of the wide varieties in its clinical appearance, histopathology, immunology, and treatment response. In atypical variations of cutaneous tuberculosis, one needs to depend on examinations like histopathology, AFB examination, culture, or polymerase chain response (PCR) for confirmation [5].

Hyperkeratosis, parakeratosis, elongation of rete ridges/ pseudoepitheliomatous hyperplasia

Granulomas in dermis

Mediastinum bodies or murrin bodies

Thin atrophic/hyperplastic epidermis with granulomas composed of giant cells, lymphocytes, plasma cells, epitheloid cells
Treatment and differentiating features of cutaneous tuberculosis was presented respectively in Table 1 and Table 2 [4,5,6-11].

CONCLUSION

Any patient presenting with multiple nodules and verrucose plaque a diagnosis of TBVC should never be missed.

CONSENT

The examination of the patient was conducted according to the Declaration of Helsinki principles.
