ABSTRACT

Eponyms are used almost daily in the clinical practice of dermatology. And yet, information about the person behind the eponyms is difficult to find. Indeed, who is? What is this person’s nationality? Is this person alive or dead? How can one find the paper in which this person first described the disease? Eponyms are used to describe not only disease, but also clinical signs, surgical procedures, staining techniques, pharmacological formulations, and even pieces of equipment. In this article we present the symptoms starting with (S) and other. The symptoms and their synonyms, and those who have described this symptom or phenomenon.

Key words: Eponyms; Skin diseases; Sign; Phenomenon

Saber Shin sign

The sharp delimitation characteristic of a syphilitic skin lesion and Scars on the mouth following the healing of lesions in congenital syphilis [1]. Anterior bowing of the tibia, seen in some children with congenital syphilis (Fig. 1). Also known as Fournier’s sign.

Jean Alfred Fournier

French dermatologist, 1832-1914 (Fig. 2). He specialized in the study of venereal diseases. In 1876 he was appointed chef de service at the Hôpital Saint-Louis, and in 1880 became a member of the Académie de Médecine. His main contribution to medical science was the study of congenital syphilis, of which he provided a description of in 1883. In his numerous publications he stressed the importance of syphilis being the cause of degenerative diseases. His name is associated with the following three medical terms: Fournier’s gangrene: Gangrene caused by infection of the scrotum and usually associated with diabetes. Although the condition is named after Fournier, it was first described by a physician named Baurienne in 1764. Fournier’s sign, Fournier’s tibia [2].

Sabia sign

South America fever and bleeding caused by the zoonotic Brazilian hemorrhagic fever Arenaviridae virus [3].

Sacral sign

Pitting oedema over the sacrum [4].

Saint Gervasius’s sign

During the Middle Ages, “St. Gervasius’ disease” became a popular name for any rheumatic affliction.
During the Middle Ages, “St. Gervasius’ disease” became a popular name for any rheumatic affliction. St. Gervais-les-Bains has been a well-frequented spa on the Bon-Nant River in Southeast France since Roman times. It would be hard to ascertain if the disease was named after the saint or the town. Benjamin Lee Gordon, the medical historian, noted that the eponym was derived from the Babylonian and Persian. According to the St. Andrew Daily Missal, Sts. Gervase and Protase, sons of St. Vitalis and St. Valeria, “were martyred under Nero at Milan (first century). Gervase was beaten to death and Protase, after having been scourged, was beheaded.” Whether St. Gervase was afflicted with a rheumatic disease is not revealed [5].

Saint Giles’s sign

The epicentre of the Great Plague of 1665 was also the location of London’s primary medieval leprosy hospital. To the likes of Samuel Pepys, Nell Gwynn and Charles II, St Giles in the Fields was London’s largest outer parishes. Close to the capital’s burgeoning playhouses, it was a dirty, disorganised and poverty-stricken suburb of ramshackle tenements (just under 2000 households in total) and narrow streets, containing inns, brothels, butchers, watchmakers, booksellers, beltmakers, justices of the peace and nobility. Cosmopolitan and heavily populated, at its centre was the parish church of St Giles in the Fields, rebuilt in the late 1620s/early 1630s upon the site of the medieval original. It was a place that became synonymous with plague and the deaths of tens of thousands of Londoners.

In the early twelfth century, the space that the London parish of St Giles in the Fields would later occupy was a green expanse of open fields and fresh air, well outside the capital. The only sign of habitation came from a newly-built hospital or ‘leprosarium’, that provided sanctuary for ‘lepra’ sufferers, away from the populous of London. At the time of the hospital’s foundation, the word ‘lepra’ (from the Latin ‘sclaty’) was a catch-all term used to describe those suffering from a range of debilitating skin conditions, such as eczema, psoriasis, skin cancer. As well as being one of the earliest in England, St Giles was also the first leprosarium associated with London. St Giles was positioned on the main throughway to London from the west. The arrival of The Black Death in 1348, and its undeniably contagious nature, led to a fear – for the first time – that leprosy might also spread through miasma (the Galenic idea of ‘bad air’). St Giles was no exception. In 1542, a burial ground was annexed to the church. As London swelled, the village of St Giles grew in tandem and became the parish of St Giles in the Fields. By 1665, it had transformed into an overcrowded London suburb, notorious for its poverty and crime, and the burial place of over three thousand plague victims [6].

Saint Giles’s Black sign

Saint Giles (c. 650 AD – c. 710), is a Patron Saint of Breast Cancer (Feast Day - September 1st) [7].

Saint Guy’s sign

Dancing in wild delirium often for many hours accompanied with an irrational fear of demons and drowning in blood, as well as, sometimes visions of heaven and the Savior enthroned with the Virgin Mary. An indication of ergot poisoning. Also known as chorus sancti viti, the lascivious dance, choromania, tanzplage,
and orchestromania. Most commonly called Dancing Madness Sign [8].

**Saint Job’s sign**

In the 15th and 16th centuries, people sought to protect themselves against a new disease that the physician Gaspare Torella (1452-1520) named the scourge of God. In seeking comfort in faith and prayer for God’s forgiveness, the supplicants prayed to the saints to intercede on their behalf to recover from this new disease of syphilis, which was identified variously by the saints’ names. Syphilis became known as Saint Mevenno disease, Saint Minus disease, Saint Mento disease, Saint Maino or Saint Job disease [9]. Saint Job disease (male de Y ob or Giobe disease, Giobbe disease, or le fiebres Sainck Y ob) refers to the biblical Job, who patiently accepted all the plagues that affected him.

**Saint Lazare’s sign**

Synonym of Leprosy. The Military and Hospitaller Order of St. Lazarus of Jerusalem (OSLJ) is a religious/military order of chivalry which originated in a leper hospital founded by Knights Hospitaller in the twelfth century by Crusaders of the Latin Kingdom of Jerusalem. Sufferers of leprosy regarded the beggar Lazarus as their patron saint and usually dedicated their hospices to him. His name corresponds to Hebrew יֵרֵעַל ‘el’ azar (“God saved”) [10].

**Saint Louis headache sign**

Fever, headache, disorientation, coma, encephalitis with cerebellar involvement, can progress to mortality. Caused by the bite of a mosquito infected with the zoonotic St. Louis encephalitis flavivirus [11].

**Saint Main’s Evil sign**

The sign of a patient suffering from scabies. Also called Saint Main’s disease.

**Saint Rochs sign**

Synonym of plague [12]. Saint Roch is a patron saint of plague victims.

**Saint Semen’s sign**

Synonym of syphilis.

**Saldana sign**

Fever, pancytopenia, hepatosplenomegaly, caused by the zoonotic transmission of a protozoal Leishmania species by the bite of phlebotomine sand flies. The disease can exist in visceral, cutaneous, and mucosal forms [13,14].

**Salt sign**

A form of enzootic marasmus due to a cobalt deficiency [15].

**Saluting sign**

The “allergic crease” together with the “allergic shiner” (darkening of the lower eyelid) and the “allergic salute” constitute the three facial hallmarks of these patients. This is the characteristic habitual gesture of wiping and/or rubbing the nose in an upwards or transverse manner with the fingers, palm, or back of the hand. It is termed a salute because the upward movement of the hand acts as an unintentional gesture [16].

**Samitz’s sign**

Dystrophic and ragged cuticle seen in dermatomyositis is called as Samitz sign [17,18].

**Sandal sign**

The gap between the first and second toes is a typical finding in trisomy 21 (Fig. 3). The feet are broad and short. The plantar surfaces are creased with a deep long furrow (ape-line) between the first and second toes [19]. Also called as “thong sign”.

---

*Figure 3: Sandal sign*
**Sandwich sign**

In dermatophytosis, fungi are present in the horny layer between two zones of cornified cells, the upper being orthokeratotic and lower consisting partially parakeratotic cells (Fig. 4) [20].

**Sandworm sign**

Inflammation and spiral erythema on the inner side of the sole [21,22].

**Schönlein’s sign**

Purpura rheumatica (Fig. 5). Also called Schönlein’s disease [23-25].

**Johann Lukas Schönlein**

German physician, 1793-1864 (Fig. 6). Johann Lukas Schönlein is reckoned among the most important medical scientists of the Biedermeier Zeit, the period following the Napoleonic wars, 1815 to 1858, in Germany. The work of Schönlein contributed greatly to the establishment of medicine as a natural science and, above all, to the development of modern methods in the teaching and practice of clinical medicine.

Schönlein grew up in a Bamberg which was one of the cradles of German hospital medicine. His interests however, were not in medicine, but in natural knowledge, which experienced a period of scientific advances in the beginning of the nineteenth century.

In 1811 he began his studies of the natural sciences, particularly under Georg Augustin Bertele at the University of Landshut. Schönlein changed his course to that of medicine, and already whilst a student he sought beyond the ordinary medical curriculum and concerned himself with comparatory anatomy, particularly under Friedrich Tiedemann. One of his other important teachers in the main curriculum was Martin Muenz.

In 1813 Schönlein went to Würzburg to continue his education. His special field of interest was the anatomy of the brain, which was the topic for his doctoral thesis in 1816, Von der Himmetamorphose - an unusually long dissertation of 140 pages that clearly demonstrates his inclination towards natural philosophy. After receiving his doctorate, Schönlein in 1816 left Würzburg, still not considering a clinical career. Hoping for a position with the Dutch East India Company, to have the opportunity to undertake studies in natural history.

In the autumn of 1817, by the support of Döllinger, Schönlein was habilitated as Privatdozent at the University of Würzburg. In the spring of 1818 he commenced lecturing on pathological anatomy,
Schönlein’s description of purpura rheumatica was written down by his students and published in Allgemeine und specielle Pathologie und Therapie, a work containing true empirical medicine. In it he described the petechias and the associated joint troubles - Schönlein’s purpura [26].

**Screwdriver Teeth sign**

There are depressions or notching of the incisal edges of the labial surfaces of the permanent incisors (Fig. 7). A sign of congenital syphilis [27]. Also called Hutchinson’s Incisor sign or Teeth sign.

**Sir Jonathan Hutchinson**

English surgeon and pathologist, 1828-1913 (Fig. 8). In 1851 he studied ophthalmology at Moorfields and was an ophthalmologist to the London Ophthalmic Hospital. He was also venereologist to the Lock...
Hospital, physician to the City of London Chest Hospital, and general surgeon to the London and Metropolitan Hospitals. From 1859 to 1883 he was surgeon to the London Hospital, and he also worked at the Blackfriars Hospital for Diseases of the Skin, being elected to the staff in 1867 and becoming senior surgeon. Hutchinson developed a special interest in congenital syphilis, which was common in London in his time, and he was responsible for delineating the natural history of the disorder. It is said that he saw more than one million patients with syphilis in his lifetime. Hutchinson had a vast clinical experience and he published his observations in more than 1,200 medical articles. Despite his busy practice he produced the quarterly Archives of Surgery. For a brief period of time he was the editor of the British Medical Journal. In England the term morbus Hutchinson-Boeck has been used for benign lymphogranulomatosis, now commonly known as Boeck’s sarcoid. In January 1869, a 58 year-old coal-wharf worker, John W, attended Jonathan Hutchinson at the Blackfriars Hospital complaining of purple skin plaques, which had gradually developed over the preceding two years, somewhat symmetrically on his legs and hands. They were neither tender nor painful and did not ulcerate. Hutchinson considered that the skin lesions were in some way related to the patient’s gout. His name is associated with: Bernard-Horner syndrome (Claude Bernard), Hutchinson’s angina, Hutchinson’s dehidrosis, Hutchinson’s disease, Hutchinson’s facies, Hutchinson’s freckle, Hutchinson’s mask, Hutchinson’s melanotic disease, Hutchinson’s patch, Hutchinson’s prurigo, Hutchinson’s pupil, Hutchinson’s sign 2 (Sir Jonathan Hutchinson), Hutchinson’s teeth, Hutchinson’s triad, Hutchinson-Gilford disease [28].

**Scratch sign**

This sign is to be elicited in patients having pityriasis versicolor, wherein the barely perceptible scales are made to stand out by scratching the lesion with fingernail [32]. Also called as coup d’ongle sign, Besnier’s sign or stroke of the nail.

**Seat Rash sign**

Sign from IndoChina, c. 19th century. Described urticarial buttocks lesions on French soldiers, caused by the zoonotic Strongyloides stercoralis roundworm [33].

**Seeping sign**

Just after birth a seemingly healthy child begins to bleed from the mucous surfaces and from the navel [34]. A sign of syphilis haemorrhagic neonatorum. The first survey was made by Mraček, who described a series of cases of syphilis haemorrhagica neonatorum and demonstrated the pathologic changes in blood vessels and capillaries. In 1875 Bälz described 3 cases of hemorrhagic syphilis. One patient suffered from a papulosquamous syphilid with capillary bleeding combined with hemorrhage from different points and in the lungs.

**Seoul Fever sign**

Rapid fever, kidney failure, severe back pain, and bleeding rash which progresses to death in 15 percent of victims [35]. Caused by a zoonotic hantaviral infectious process known as hemorrhagic fever with renal syndrome disease.
Septic sign

A disease which arises from the development of pyogenic or putrefactive organisms [36].

Serpent sign

Keratolysis or deciduous skin, a condition in which the whole skin is cast off like a snake in huge contiguous pieces. Also called Preston’s sign. Deciduous skin can be defined best as continuous, periodic or seasonal shedding or peeling of the epidermal layer of the skin of more or less generalized distribution [37].

Setting sun sign

The setting-sun phenomenon is an ophthalmologic sign in young children resulting from upward-gaze paresis. In this condition, the eyes appear driven downward, the sclera may be seen between the upper eyelid and the iris, and part of the lower pupil may be covered by the lower eyelid. Pathogenesis of this sign is not well understood, but it seems to be related to aqueductal distention with compression of periaqueductal structures secondary to increased intracranial pressure. However, it can also be transiently elicited in healthy infants up to 7 months of age by changes of position or removal of light (benign setting-sun phenomenon). The benign form might represent immaturity of the reflex systems controlling eye movements. When persistent, this sign is one of the most frequent markers of elevated intracranial pressure, appearing in 40% of children with hydrocephalus (of any cause) and in 13% of patients with ventriculoperitoneal shunt dysfunction. It is an earlier sign of hydrocephalus than enlarged head circumference, full fontanelle, separation of sutures, irritability or vomiting. Consequently, this sign is a valuable early warning of an entity requiring prompt neuroimaging and urgent surgical intervention [38].

Shaven Beard sign

Peyer’s patches seen post mortem due to typhoid fever [39].

Shawl sign

Oedematous-erythematous lilac coloured skin lesions may be also present in the skin of decolletage and shoulders as the shawl sign (Fig. 9) [18,40].

Sheep Dip sign

Severe spreading stomach pain with possibly vomiting black from soot or blue from indigo. Intense thirst, cramps, and coma [41]. Also known as Arsenic sign (acute) and Paris Green sign.

Shelly’s sign

A sago like eruption on the palate and the lips [42]. A sign seen in influenza.

Sheklakov sign/False Nikolskiy sign

This sign is positive in subepidermal blistering disorders, like bullous pemphigoid, cicatricial pemphigoid, herpes gestationis, dermatitis herpetiformis, linear IgA bullous dermatitis, epidermolysis bullosa acquisita, junctional and dystrophic epidermolysis bullosa, porphyrias and bullous SLE.

This involves pulling the peripheral remnant of a roof of a ruptured blister, thereby extending the erosion on the surrounding normal appearing skin. It is called the “false Nikolskiy” sign because it is a subepidermal cleavage occurring in the perilesional skin. The erosions thus induced are limited in size, do not exhibit tendency to subsequent spontaneous extension and heal rapidly [43,44].

Nikolay Dmitriyevich Sheklakov

Russian dermatologist (1918-1989), (Fig. 10), who was Professor and Chairman of the Department of Dermatology and Venereology at the Moscow School of Dentistry, Moscow, Russia (then the Union of Soviet Socialist Republics), described the sign of perifocal...
subepidermal separation (“false Nikolskiy sign”), which is also known in the modern dermatologic literature published in Russian as the Sheklakov sign. In contrast to the true Nikolskiy sign, perifocal subepidermal separation is induced at the periphery of blisters with a subepidermal location by pulling the remnant from the blister roof or wall. The induced erosions are limited in size, do not have a tendency to subsequent spontaneous extension, and heal fast [45].

Ship-fever sign

Epidemic typhus (Fig. 11) (also called “camp fever”, “jail fever”, “hospital fever”, “ship fever”, “famine fever”, “putrid fever”, “petechial fever”, “Epidemic louse-borne typhus” and “louse-borne typhus”) is a form of typhus so named because the disease often causes epidemics following wars and natural disasters. The causative organism is Rickettsia prowazekii, transmitted by the human body louse (Pediculus humanus corporis) [46-48].
