ABSTRACT

Vulvar lymphangioma circumscriptum (LC) is an unusual benign condition, congenital or acquired, related to interference in the lymph drainage. This entity can be confused with conditions such as genital warts. We sought to clarify the clinicopathologic features of the Acquired vulvar LC by studying 3 affected patients from our institution. We report 3 cases of vulvar LC: Two cases were presented after gynecologic cancer treatment (surgery, lymphadenectomy, and radiotherapy). 1 case was related to lower limb chronic lymphedema. In two of them, the initial clinical diagnosis was genital wart. Two patients were treated by Laser CO2 and cryotherapy, with a good response and without any recurrence. The possibility of vulvar LC should be taken into account as a possible diagnosis in patients with previous oncological surgery or genital warts refractory to the conventional treatment. Knowledge on the features of this lesion can avoid unnecessary clinical and therapeutic procedures.

Key words: Acquired; Vulvar; Lymphangioma circumscriptum

INTRODUCTION

Lymphangioma circumscriptum (LC) is a rare vascular malformation that affects the lymph vessels of the papillary dermis. LC can be either congenital or acquired after damaging the previously normal lymph channels [1]. It frequently appears in the armpit, the neck, and the proximal portion of the extremities [2]. Acquired vulvar LC (AVLC), is a rare, benign condition [3]. Most of the descriptions refer to isolated cases or short series of patients. We report 3 cases and describe the clinical and pathologic characteristics, to add to the limited data present in the literature.

CASE REPORTS

We report 3 cases of AVLC. The summary of the clinical features of our serie is shown in table 1. Ages ranged from 46 to 72 yr (average 60 yr). Two cases were presented after gynecologic cancer treatment (surgery, lymphadenectomy, and radiotherapy) (Figs. 1A and B). One case was related to lower limb chronic lymphedema (Fig. 1C). The average range of the lapse of time between the onset of the predisposing factor and the LC onset was 6 yr (ranging between 2 and 10 yr). In our patients, LC presented with the same lesions: they had several verrucous papules with intervening normal skin (Figs. 1A - C). A careful dermoscopic examination of the lesions showed the following features: lacunae, vascular structures and white lines. All lesions had a light background colour (Fig. 2). The initial clinical diagnosis in 2 of the cases was condyloma and were treated by electrocoagulation and trichloacetic acid, without improvement. Histopathologic findings were similar in all biopsy specimens. All lesions showed the presence of variably dilated vessels located within the superficial papillary dermis. These were lined by a single layer of endothelial cells with flat nuclei. The dermis between them did not show the presence of inflammation (Fig. 3). Morphologic features suggesting infection by human papillomavirus or dysplasia were not found. two patients were treated by Laser CO2 and cryotherapy, with a good response. The third patient refused a treatment and a conservative treatment was performed.
Prior to the study, patient gave written consent to the examination and biopsy after having been informed about the procedure.

**DISCUSSION**

The AVLC, is a rare entity, as evidenced by less than 100 cases in the literature. Median age at diagnosis for acquired VLC is 52 years [4]. The lapse of time between
the onset of the predisposing factor and the presentation of the LC is usually prolonged, from 3 to 40 years.

The AVLC is a long-term complication caused by different etiologies [5]. In most cases, the AVLC are associated to malignancy. It usually arises after radical surgery or cervical cancer radiotherapy. However, there have also been cases after treatment for vulvar cancer, endometrial cancer, or melanoma [3]. A large obstructive pelvic malignancy could lead to VLC (4). It is less often found in non oncological etiologies such as: Crohn disease [5], genital tuberculosis [6], chronic lymphedema [7], or local infectious diseases (acute cellulitis or hidradenitis suppurativa) [8]. Obesity could also have played a role in the development of LC. Several cases in the literature are without known cause [9].

The clinical presentation of ALV is highly variable, ranging from being asymptomatic to a highly disabling condition. Discomfort, itching, rubbing and lymph oozing are the most frequent symptoms [10]. Clinically, ALV usually presents as multiple nodular lesions, verruciform or polypoid, with variable size and, usually, with intervening normal skin. VLC sometimes accompanies lower extremity edema, or genital lymphedema. VLC may pose diagnostic difficulties both clinically and histopathologically. ALV is frequently confounded with warts or condyloma acuminata [11]. The most common dermoscopic pattern associated with ALV is the presence of lacunae and vascular structures. The hypopyon sign and the white or yellowish coloration of lacunae are very characteristic of lymphangioma circumscriptum [12]. Histopathologically, LC is characterized by the presence of dilated lymphatic channels in the papillary dermis. They have a cystic appearance and are layered by a normal-appearing endothelium. The overlying epidermis can show variable degrees of acanthosis and hyperkeratosis [9].

The management of vulvar LC is not standardized and many different treatments with varying results have been proposed. Therapeutic options include surgical excision, yttrium–aluminium–garnet laser, cryotherapy, sclerotherapy, CO2 laser, or electrocoagulation. Conservative treatment is suitable in some cases and, probably, It’s the best choice in asymptomatic cases, because of the high recurrence rate in all modalities of treatment [4].

CONCLUSION

VLC is a very rare disease, causing major discomfort, aesthetic prejudice and risk of infection. it is important to make clinicians aware of this entity so that it can be recognized more rapidly, and to prevent misdiagnosis and unnecessary treatments. when vulvar condylomas or warts are refractory to medical treatment, performing a biopsy should be considered in order to confirm the histology of the condition.

CONSENT

The examination of the patient was conducted according to the Declaration of Helsinki principles.
