ABSTRACT

Background: Pruritic papular eruption of HIV (PPE-HIV) has been well described in some sub-Saharan Africa countries and elsewhere, with varying geographical prevalence. Aims: To determine the frequency and the clinico-topographic distribution of these lesions as seen in the University of Benin Teaching Hospital, Benin-City, Nigeria and to compare our findings with those seen in other parts of the world. Materials and Methods: This study was carried out at the University of Benin Teaching Hospital (UBTH), Benin-City. University of Benin Teaching Hospital is an 800-bed Federal Government tertiary hospital which offers both in-patient and out-patient services. Specimen collection and analysis of the study lasted 18 months (January, 2015 to June, 2016). All HIV patients at presentation in clinic and wards with suspicion of PPE during the study period were interviewed examined. Qualitative variables were described in percentages and proportions. Continuous variables were summarized as mean and standard deviation when normally distributed. Results: A total of 106 patients were studied, there were 41 (38.7%) males and 65 (61.3%) females with a male to female ratio of 1:1.6. Their mean age was 40.2±10.4 years. Majority (79.3%) of patients had at least secondary education and males were slightly better educated than females. Most (33.0%) of the subjects were traders, the mean duration of diagnosis of PPE was 5.22±3.92 and 6.05±5.21 months for males and females respectively, while the overall mean duration of diagnosis of PPE was 5.73±4.75 months. The most commonly reported sites initially affected by PPE among the patients were lower limb (51.0%) and upper limb (39.6%). Conclusion: Majority of lesions of Pruritic papular eruptions (PPE) of HIV in this study were found in educated females. The mean age of distribution of PPE was found in the 4th decades. Furthermore PPE is distributed predominantly on the exposed parts of the body especially the upper and lower limbs.

Key words: Human Immuno-deficiency Virus; Pruritic papular eruption; clinic-topographic

INTRODUCTION

Pruritic papular eruption of human immunodeficiency virus (PPE-HIV) is one of the most common dermatologic disorders in untreated HIV-infected adults. Pruritic papular eruption of HIV (PPE-HIV) has been well described in some sub-Saharan Africa countries and elsewhere, with varying geographical prevalence.¹ Report of PPE emerged early in the course of the HIV epidemic as far back in 1983 in series of studies conducted in Democratic Republic of Congo [1], Mali [2], Nigeria [3], Tanzania [4], Togo [5], Zambia [6], and other Africa countries, where it was described as an extremely pruritic diffuse skin eruption occurring in HIV infected patient.

Studies have it that between 11% and 46% of HIV positive patients are affected with PPE, depending on the geographical location [7,8]. In Haiti it accounted for 46% [7], Thailand (33-37%) [8], in Zaire among

hospitalized patients (18%) [9], Kenya (5%) [10], and (16.7%) in Nigeria [11].

There are few reported cases of pruritic papular eruption of HIV in United States of America (USA), except in areas with high mosquito prevalence such as Southern Florida [12], where a PPE prevalence of 11% was reported by Goldstein et al [13].

Only few studies on Pruritic papular eruption of HIV have been done in Nigeria and as such there is the need to study PPE cases as they present to the University of Benin Teaching Hospital.

The main objective of this study is to determine the frequency and the clinic-topographic distribution of these lesions as seen in the University of Benin Teaching Hospital, Benin-City, Nigeria and to compare our findings with those seen in other parts of the world.

MATERIALS AND METHODS

Study Area

This study was carried out at the University of Benin Teaching Hospital (UBTH) Benin-City. UBTH is an 800-bed Federal Government tertiary hospital which offers both in-patient and out-patient services. It is located in Egor Local Government Area of Edo State, Nigeria. It receives referrals from Edo state and neighbouring States like Delta, Ondo, Anambra, Ekiti, Kogi, and Bayelsa.

Study Duration, Design and Population

Specimen collection and analysis of the study lasted 18 months (January, 2015 to June, 2016) after approval by the ethical committee. The study design was a cross-sectional descriptive study of confirmed HIV-infected patients with clinically active PPE lesions presenting at the Dermatology outpatient clinic, the HIV/ART clinic of the Dermatology and Infectious disease unit of Internal Medicine department of UBTH and those admitted as in-patients in the medical wards of the UBTH.

Sampling Method

All HIV patients at presentation in clinic and wards with suspicion of PPE during the study period were interviewed examined and skin biopsy sample taken and patients with histological evidence of PPE were consecutively recruited into the study until the required sample size was attained.

Data Analysis

Data generated from the study was entered into and analyzed using the Statistical Package of Social Science (SPSS) version 21. Qualitative variables were described in percentages and proportions. Continuous variables were summarized as mean and standard deviation when normally distributed. Non–normally distributed quantitative variables were summarized as median. The findings were presented in appropriate tables.

RESULTS

Social Demographic Characteristics of the Patients

A total of 106 patients were studied and their findings presented below. There were 41 (38.7%) males and 65 (61.3%) females with a male to female ratio of 1:1.6. Their mean age was 40.2±10.4 years. The males (mean=40.9±8.8 years) were slightly older than females (mean=39.7±11.4 years). Majority (79.3%) of patients had at least secondary education and males were slightly better educated than females. Thirty-eight (35.8%) of patients were single, 48 (45.3%) were married, 12 (11.3%) were widowed and 4 respondents each (3.8%) were divorced or separated. A higher proportion of males (48.8%) than females (43.1%) were married, while more females (38.5%; 13.9%) than males (31.7%; 7.3%) were single or widowed respectively. Most (33.0%) of the subjects were traders, while house-wives constituted the least (5.7%) based on occupational status - Table 1.

Duration of Diagnosis of PPE by Gender

Table 2 show the mean duration of diagnosis of PPE was 5.22±3.92 and 6.05±5.21 months for males and females respectively, while the overall mean duration of diagnosis of PPE was 5.73±4.75 months. A higher proportion of male subjects were diagnosed earlier (≤6 months) than the female, however there was no significant difference between the sexes by duration of diagnosis.

Initial (First) Part of the Body Affected by PPE Lesions according to Gender

The most commonly reported sites initially affected by PPE among the patients were lower limb (51.0%) and upper limb (39.6%), while the face is the least affected
initially among all the patients, and there was also no 
significant difference in the site first affected by gender 
as shown in Table 3.

### Distribution of Patients with PPE according to 
BMI Class

Forty-four (41.5%) of the patients were underweight, 
55 (51.9%) had normal weight and 7 (6.6%) of the 
participants were overweight as shown in Table 4. Overall 
mean BMI of all the patients was 19.2±3.5 kg/m². Mean 
BMI of the females – 19.8±3.8kg/m² was slightly 
higher than the mean BMI of the male - 18.3±2.8kg/m². 
(Table 4)

### DISCUSSIONS

In this study majority of patients with pruritic papular 
eruption of HIV were women (61.3%). This was similar 
to the findings by Mawenzi et al [10] in Kenya where 
70% of his study population were females. A similar 
observation was made by Resneck et al [14] who reported 
that 81% of PPE patients were females. Other studies 
in Kenya[10] also reported that 70% of patients with PPE 
were female. These were in contrast to a study from the 
Democratic Republic of Congo by Colebunder et al 
who stated that the frequency of PPE seen in male 
and female were approximately equal [9]. The reason for 
the disparity is unknown. Perhaps the greater susceptibility 
of female to HIV infection may explain the gender 
differences in HIV prevalence [15]. It may also mean 
that women are more skin health and cosmetically 
conscious and do seek treatment better than men as 
observed in Cameroon by Josephine et al [16]. and in 
Benin city, Edo state by Òmuemü et al [17].

The mean age of the participants in this study was 
40.2±10.4 years. This was comparable to a study done 
in Uganda where the mean age of participants was noted 
to be 35±8 years [18]. A study in India reported that the 
mean age of the PPE patients was 34.2±7.5 years [19]. 
Most of the patients with PPE in this study (68.8%) 
were less than 45 years old, in keeping with the age 
group more likely to be HIV infected as reported in 
similar studies in our environment [20,21].

Majority of patients (79.3%) in this study had at least secondary education and above. This was in keeping 
with a previous study by Egube et al in Benin City 
that corroborated to high literacy level among the 
inhabitants of Benin City and its environs [22].

| Table 1: Socio-demographic Characteristics of the Patients by Gender |
|-----------------------------|-----------------------------|-----------------------------|
| Characteristic               | Male n=41 (%)              | Female n=65 (%)             | Total n=106 (%)              |
| Age (in years)               |                             |                             |                             |
| 15-29                       | 2 (4.9)                     | 15 (23.1)                   | 17 (16.0)                   |
| 30-44                       | 26 (63.4)                   | 30 (46.2)                   | 56 (52.8)                   |

| Mean±SD                                                      | 18.3±2.8                    | 19.8±3.8                    | 19.2±3.5                    |
The mean duration of PPE skin lesion as reported by participants before diagnosis was 5.73±4.75 months. This was comparable to the findings of Lakshmi et al [23] in India who reported mean PPE duration of 6.5 months at diagnosis. A study done in Uganda found out that majority (58%) of PPE patients had PPE for more than 6 months at diagnosis [24]. The time lag before patient presentation to the clinic and the intense pruritus could have been responsible for the secondary changes noticed in patients with this skin lesion.

In addition to its presence in large number of patient, PPE is often one of the early cutaneous manifestations of HIV. In a study done in Kenya by Mawenzi et al [10] on the epidemiology and clinical spectrum of cutaneous disease manifesting among newly diagnosed HIV seropositive adult in Kenya; it was reported that out of 394 cases 20 patients accounting for 5% had PPE. PPE is often one of the early cutaneous manifestations of HIV. Liautaud et al [25], in a study of PPE-HIV in Haitian patients, observed pruritic papular skin lesion as the initial symptom in 70% of patients and similar findings were described in Democratic Republic of Congo, by Colebunder et al [9], where 51% reported that the skin eruption was their initial manifestation of HIV.

Pruritic papular eruptions (PPE) are characterized by chronic pruritus and symmetric papular eruptions on the trunk and extremities, with absence of other definable causes of itching in an HIV-infected patient [15,26]. The face may be involved in some patients and the condition tends to wax and wane [16,23].

The review of body parts affected by the rash in this study showed that majority (98.1%) of the patients with Pruritic papular eruptions of HIV have the lesions on their extremities as shown in Figs 1 and 2. Other investigators have reported that the lesions of PPE were mostly located on the extremities [11,25,27].

The nutritional status of PPE patients were assessed using body mass index (BMI). It was noted in the study centre, that 41.5% of the study population were under-weight while 51.9% had normal weight. The reason for the under nutrition recorded in 41.5% of patients in this study could be due to advanced immunosupression which could be associated with opportunistic infection. More so, it is documented that disease progression and viral load increments in HIV patients lead to overproduction of cytokines such as TNF that culminates in weight loss [28].

CONCLUSION

In conclusion majority of lesions of Pruritic papular eruptions (PPE) of HIV in this study were found in females and were educated. The mean age of distribution of PPE was found in the 4th decades. Furthermore PPE is distributed predominantly on the exposed parts of the body especially the upper and lower limbs.

Statement of Human and Animal Rights

All procedures followed were in accordance with the ethical standards of the responsible committee on human experimentation (institutional and national) and with the Helsinki Declaration of 1975, as revised in 2008.

Statement of Informed Consent

Informed consent was obtained from all patients for being included in the study.
