Sir,

Lipedema (or the “pole leg” disease) is a rare and painful disorder of the adipose tissue. It mainly affects females and is generally misdiagnosed as lymphedema or obesity. It may progress to involve the venous system (venolipedema) or the lymphatic system (lympholipedema), adding to the difficulty in its diagnosis. Herein, we report a case of lipedema with genital lymphatic vesicles.

A 56-year-old female presented herself with a symmetrical increase in the volume of both lower limbs persistent since a young age, painful and with repetitive bruising. The patient reported the same condition in her 45-year-old sister. A clinical examination revealed a bilateral and symmetrical enlargement of the legs without the involvement of the feet, with a sharp demarcation between normal and abnormal tissue at the ankle. The skin was firm in consistency, irregular, painful on pressure, and of a normal color. Stemmer’s sign was absent (Fig. 1). A genital examination revealed papillomatous formations, which failed to whiten after the application of acetic acid and which corresponded to lymphatic vesicles and not to condylomas (Fig. 2). The patient was advised to lose weight, engage in regular physical activity with lymphatic drainage sessions, and wear compression stockings. Moreover, the lymphatic vesicles were not touched because of the risk of lymphorrhoea.

Lipedema is considered to be a rare disorder of the adipose tissue. Its etiology is unknown and its pathophysiology is not clearly elucidated [1]. Lipedema exhibits sex-linked, X-linked, dominant or autosomal dominant inheritance [2]. The diagnosis of lipedema is quite frequently missed because of the clinician’s usual unfamiliarity with this condition, because of the overdiagnosis of lymphedema, and because of its occasional misdiagnosis as obesity [3,4]. Lymphedema is commonly asymmetric, without associated pain or bruising. Lipedema is bilaterally symmetrically distributed and is associated with pain, edema, and easy bruising. It commonly affects females after puberty but also during pregnancy and after menopause [2,5]. The disease progresses in three stages and the typical presentation is that of a female with bilateral “stovepipe” enlargement of the legs and without the involvement of the feet, with a sharp demarcation between normal and abnormal tissue at the ankle, referred to as the “cuff”
Lipedema is a pathological entity that poses a diagnostic problem, especially being misdiagnosed as lymphedema and, sometimes, obesity. Characteristics observed during the interrogation and clinical examination allow the diagnosis to be reached even if an association with the abnormalities of lymphatic drainage appears in some advanced cases, as in ours.

Consent

The examination of the patient was conducted according to the principles of the Declaration of Helsinki.

The authors certify that they have obtained all appropriate patient consent forms, in which the patients gave their consent for images and other clinical information to be included in the journal. The patients understand that their names and initials will not be published and due effort will be made to conceal their identity, but that anonymity cannot be guaranteed.
