A disorder first described by Zoon in 1952, Zoon’s balanitis or Plasma cell balanitis (PCB), is an uncommon clinical disorder seen in middle-aged uncircumcised men. It is characterized by one or more indolent well demarcated, glazed, reddish brown patches on the glans penis or prepuce. The etiology of this disease is unknown. This balanitis does not respond to routine topical antifungals, steroid creams and systemic antifungals. Diagnosis is confirmed by biopsy. Herein we report 8 cases of PCB, presenting with a characteristic clinical picture of the disease. In all cases circumcision was done and histopathology confirmed the diagnosis of PCB. All patients were followed up for a period of 6 months and no recurrences were observed. Development of malignancy is not seen. In conclusion. We believe that for all cases of balanitis, not responding to routine topical antifungals, steroid creams and systemic antifungals, the diagnosis of Zoon’s balanitis should be considered.

**Streszczenie**

**Key words:** plasma cell balanitis; Zoon’s balanitis; circumcision

**Key words:** zapalenie plazmacytowe żołędzi; zapalenie żołędzi Zoona; obrzezanie
There was no history of exposure to sexually transmitted infections, diabetes or urethral symptoms. The first patient gave a history of application of soframycin cream. Examination of these patients showed erythematous plaque over glans penis in six of them and in two, lesions extended onto prepuce (Fig. 1,2).

These cases were treated with topical and systemic antifungals and also with mild corticosteroid cream for 3 months with no response. In one case topical tacrolimus 0.03% application cleared the lesions but recurrence was seen within 3 months.

In all cases, circumcision was performed and a biopsy was sent for histopathological examination. Results indicated that the features of these were consistent with Plasma cell balanitis (Fig. 3,3a,4). These cases were followed-up for 6 months and no relapses were observed. Assessment of diabetic neuropathy was done on the basis of the criteria detailed by Foster [7]. Relevant microbiological and histopathological investigations were carried out to confirm the clinical diagnosis.

Discussion

Plasma Cell balanitis (PCB) or “balanitis circumscripta plasma cellularis” is a benign, idiopathic condition first recognized by Zoon in 1952. Zoon described eight cases of chronic balanitis with unique benign appearing histologic findings previously diagnosed as Erythroplasia of Queyrat [1-3].

Plasma cell balanitis typically presents as a solitary, smooth, shiny, red-orange plaque on the glans and or the prepuce of an uncircumcised, middle-aged to older man. The lesion often exhibits pinpoint purpuric cayenne pepper surface spotting with a yellow hue. Vegetative, erosive variants and multiple lesions have been reported [4]. PCB tends to be chronic and is often present for months to years before the patient reports for consultation. Symptoms are minimal, but may include mild tenderness or pruritus. Diagnosis is confirmed by the distinctive histologic findings. Epidermal atrophy with complete effacement of the rete ridges is present. Ulceration may occur. Suprabasal keratinocytes are diamond shaped which are also called “lozenge keratinocytes” are common with uniform intercellular spaces termed “watery spongiosis”. A dense lichenoid subepidermal infiltrate composed largely of plasma cells is characteristic. Erythrocyte extravasation and hemosiderin deposition are often noted [5-9].

The cause of PCB is unclear. All confirmed cases have involved uncircumcised men. Heat, friction, poor hygiene, chronic infection with Mycobacterium smegmatis, trauma, response to an unknown exogenous agent, immediate hypersensitivity response to IgE class antibodies and hypospadias have been implicated as predisposing factors. A viral cause of PCB has been rejected after both PCR and electron microscopy failed to show evidence of viral particles in PCB lesions. Kossard et al postulated a causal relation between certain PCB variants and lichen aureus, in the light of similar vascular fragility and histologic abnormalities [4].

The treatment of choice for PCB is circumcision [4,5,10,11]. Successful ablation of PCB has been achieved with carbon dioxide laser and Erbium:YAG laser [12,13]. Successful treatment of vulvar analogue of PCB with intralesional interferon α has also been reported. Treatment with topical agents including corticosteroids and antifungals cause mild improvement, but the lesion usually recurs following discontinuation of treatment and are generally not curative [3,4,16]. Petersen et al found topical fusidic acid 2% cream to be beneficial [14]. Chander et al used topical tacrolimus 0.03% with success [15]. Griseofulvin has been tried without success.

This case series is being reported to make the treating clinicians aware of the clinical and histopathological features of this uncommon balanitis, and to emphasize the importance of histopathology in distinguishing this benign condition from similar looking malignant conditions and the treatment response.
