Sir,

A rare side effect of linezolid in a patient was presented in this letter. A 40-year-old woman was admitted to the hospital 1 month ago because of the lesions on her face, around the right ear. On examination, she had multiple pre-auricular and post-auricular nodular lesions and the largest one was 1.5 cm in diameter. In the patients’ previous medical history, she had a disease of systemic lupus erythematosus, diagnosed 20 years earlier that had been controlled with steroid for the previous 19 years. At the time of admission, she was receiving a combination of steroid and azathioprine for last 6 months. She was examined by magnetic resonance imaging (MRI) of the brain and multiple abscess formation was reported. Initially, trimethoprim-sulfamethoxazole (15 mg/kg) and ceftriaxone (1gr bid) was administered as empirical treatment. Initial antibiotic regimen was continued according to culture results from lesions. Nocardia species was isolated from the culture and found susceptible to ceftriaxone, trimethoprim-sulfamethoxazole and linezolid. At the second week of the antibiotic therapy, the lesions showed progression and pneumatic infiltration was developed. For this reason, trimethoprim-sulfamethoxazole regimen was switched to linezolid (600 mg bid). A black hairy discoloration on her tongue, especially right side appeared 10 days after initiating linezolid therapy (Fig. 1a). The patient denied any use of tobacco or alcohol. Despite this side effect, she well tolerated the therapy with linezolid. Nearly one week later, patients’ tongue completely resolved with just brushing and applied a good oral hygiene (Fig. 1b). Black discoloration of tongue is a reaction pattern that can be related to some conditions such as medications, physiologic, metabolic and toxic disorders and exogenous substances like tobacco, alcohol, and crack cocaine [1].

It can be caused by drugs such as corticosteroids, lansoprazole, methylidopa and some antibiotics (cephalosporins, claritromycin, penicillins, sulfonamids and tetracyclines) [2,3]. Linezolid is associated with some adverse events, mainly nausea, vomiting, diarrhea, and headaches. Thrombocytopenia and anemia also occur frequently in patients taking linezolid [4,5]. Black hairy tongue has been described before and the rate was reported as 0.2% in a large and controlled clinical study including 1498 patients received linezolid [5]. Although the exact pathogenesis is unclear, antibiotics such as linezolid associated black hairy tongue might change the normal flora of the mouth. The discoloration usually appeared after a few days treatment like this case [1-3].

Amir et al [6] have reported a 65-year-old kidney transplant recipient with tongue discoloration after receiving a 14 day course of linezolid. The discoloration resolved 6 months after the discontinuation of linezolid. The discoloration resolved 6 months after the discontinuation of linezolid. Ma JS [7] has also reported a case of 8-year-old girl with the diagnose of bacteremia and polyarthritis presented with discoloration of the both incisors and tongue, 1 and 2 weeks after initiating linezolid therapy.

Black hairy tongue is a benign, reversible and very rare side effect due to linezolid. It can be omitted by the physicians, for this reason, this case was presented in here.
