Abstract
Unilateral laterothoracic exanthem (ULE) (also termed asymmetric periflexural exanthem of childhood APEC) has been linked to viral infection, in particular parvovirus B-19, citomegalovirus and Ebstein Barr virus. Its prevalence is higher during spring and winter, most published reports involve white people. The diagnosis is clinical, the virusological tests, in most of the cases, are negative. The exanthem is self-limited, it resolves in four-six weeks, it requires only symptomatic treatment. Our case is particular by the appearance in a pregnant woman to whom we have not succed to identify any virus involved, with wonderful clinical results under no medication. We follow the evolution of the pregnancy.

Key words: exanthem; unilateral laterothoracic exanthem; pregnancy

Introduction
Unilateral laterothoracic exanthem (ULE) (also termed asymmetric periflexural exanthem of childhood APEC) was first described in 1962 in the United States, but the name was given in 1992 by Bodemer-de Prost [1]. It usually manifests as unilateral erythematous papules surrounded by white halo, without systemic symptoms. ULE has been linked to viral infection, in particular parvovirus B-19, citomegalovirus and Ebstein Barr virus [2]. While ULE most commonly occurs in children, ULE can occur in adults, we describe a typical case, appeared in a pregnant woman (Vth month of pregnancy) with a 2 weeks favorable evolution [1,3].

Case report
A 32 year-old woman presented in our Department with an asymptomatic 2-day history of a unilateral erythematous macular eruption on her left side of the trunk, scattered lesions on the hips, no systemic symptoms, no palpable lymph nodes. She was in good health state. She was pregnant in Vth month with her first baby.

She denied any drug intake, no previous illness, no symptoms before the onset of the eruption.
The lab investigations showed a slight anemia, leucocytosis with neutrophilia and the virusology results were negative for Parvovirus B19, Ebstein Barr virus and citomegalovirus.

We did not recommend any therapy, just daily control and the lesions faded and dissapeared in 15 days, with minor hyperpigmentation.

Discussion
Unilateral laterothoracic exanthem is also known as asymmetric periflexural exanthem in children (APEC) and it is mainly described in children between one and five years old, although adults can be affected too. Its prevalence is higher during spring and winter, most published reports involve white people [1,3].
The diagnosis is clinical, the virusological tests, in most of the cases, are negative, although ULE is linked to viruses: parvovirus B-19, citomegalovirus and Ebstein Barr virus [2]. The exanthem is self-limited, it resolves in four-six weeks, it requires only symptomatic treatment.

Our case is particular by the appearance of ULE in a pregnant woman to whom we have not succed to identify any virus involved, with wonderful clinical results under no medication. We follow the evolution of the pregnancy.
